

MKW – water coolers

Technical parameters

MKW – water cooler

- intended for circular pipes
- the casing of the water heater is made of galvanized sheet metal
- the tray for condensate draining is made of aluminum
- aluminum slats on copper tubes
- the connection is a collet transition with a thread that is not included in the delivery or by soldering (see table)
- maximum working pressure is 25 bar

Installation and operation

- the air velocity in the pipeline must not exceed 4 m/s, otherwise it is necessary to add another droplet eliminator after consultation with the EDV technical department
- mounting exclusively in a horizontal position
- an air filter must be installed in front of the cooler (protection against pollution)
- we recommend placing the cooler behind the heater
- during assembly, it is necessary to remember to drain and fill the system and ensure access for service
- as part of the projection, the cooler must be designed with regard to the amount of condensate generated

- the condensate drain with the odor siphon must be checked for the possibility of drying out and ensure a sufficient height of the water column to overcome the pressure loss of the siphon
- to determine the minimum safe level difference in the siphon, you can roughly proceed by taking the total fan pressure Pt in mm of the water column, this value will be increased by approx. 50% (the value obtained in this way represents the practical recommended value of the height of the water column in the siphon, so that the odor barrier cannot be overcome by overpressure blowing or suction by vacuum fan)
- passing air must not contain solid, fibrous, sticky and aggressive additives. It must also be free of chemical substances that cause corrosion of the materials used, i.e. destroy aluminum, copper and zinc
- based on consultation with the technical department, it is possible to offer a suitable source of cold

7¹

T1, Q1 and cold values. water 1 –
applies to supply air 32°C, RH 40 %
T2, Q2 and cold values. water 2 –
applies to supply air 25°C, RH 50 %

Notice

The cooler must be installed in the duct route with the air flow in the direction of the arrow on the cooler case. If the cooler is mounted upside down, the condensate is not led into the receiver and flows out of the cooler.

For the reliable operation of the cooler, it is necessary to ensure protection against freezing, or regulation of performance (defrosting cycle). In the order, it is necessary to state the request for right or left version.
